Collecting weather data from an API

## About the data

In this notebook, we will be collecting daily weather data from the National Centers for Environmental Information (NCEI) API. We will use the Global Historical Climatology Network - Daily (GHCND) data set; see the documentation here.

Note: The NCEI is part of the National Oceanic and Atmospheric Administration (NOAA) and, as you can see from the URL for the API, this resource was created when the NCEI was called the NCDC. Should the URL for this resource change in the future, you can search for the NCEI weather API to find the updated one.

Using the NCEI API Paste your token below.

```
import requests
def make_request(endpoint, payload=None):

return requests.get(
  f'https://www.ncdc.noaa.gov/cdo-web/api/v2/{endpoint}',
headers={
  'token': 'zFNgrNenFRaBdJfOdoxOlmalufgyOrFj'
},
params=payload
)
```

Collect All Data Points for 2018 In NYC (Various Stations)

We can make a loop to query for all the data points one day at a time. Here we create a list of all the results

```
import datetime
from IPython import display # for updating the cell dynamically
current = datetime.date(2018, 1, 1)
end = datetime.date(2019, 1, 1)
results = []
while current < end:
  # update the cell with status information
display.clear_output(wait=True)
display.display(f'Gathering data for {str(current)}')
response = make_request(
      'data',
 'datasetid' : 'GHCND', # Global Historical Climatology Network - Daily (GHCND) dataset
 'locationid' : 'CITY:US360019', # NYC
 'startdate' : current,
'enddate' : current,
 'units' : 'metric',
 'limit' : 1000 # max allowed
if response.ok:
 # we extend the list instead of appending to avoid getting a nested list
     results.extend(response.json()['results'])
# update the current date to avoid an infinite loop
current += datetime.timedelta(days=1)
     'Gathering data for 2018-12-31'
```

Now, we can create a dataframe with all this data. Notice there are multiple stations with values for each datatype on a given day. We don't know what the stations are, but we can look them up and add them to the data:

```
import pandas as pd
df = pd.DataFrame(results)
df.head()
```

Save this data to a file:

For learning about merging dataframes, we will also get the data mapping station IDs to information about the station:

```
response = make_request(
    'stations',
{
    'datasetid' : 'GHCND', # Global Historical Climatology Network - Daily (GHCND) dataset
    'locationid' : 'CITY:US360019', # NYC
    'limit' : 1000 # max allowed
}
)
stations = pd.DataFrame(response.json()['results'])[['id', 'name', 'latitude', 'longitude', 'elevation']]
stations.to_csv('/content/weather_stations.csv', index=False)
with sqlite3.connect('/content/weather.db') as connection:
stations.to_sql(
    'stations', connection, index=False, if_exists='replace'
)
```
